

SYNET Technology Internship

Task 1: Simple Calculator

1. Introduction

The Simple Calculator is a beginner-friendly command-line application developed in Python as part of the SYNET Technology Internship. It performs basic arithmetic operations based on values and an operator entered by the user.

2. Objective

The objective is to demonstrate fundamental Python programming concepts including user input, numeric values, conditional statements, arithmetic operators, and basic error handling.

3. Technologies Used

Technology	Purpose
Python 3	Programming language used to develop the calculator
CLI / Terminal	Interface for user input and output

4. Methodology

- The program displays a calculator heading.
- Two numeric values are collected from the user.
- The user enters one of the supported operators: +, -, *, or /.
- Conditional statements determine which arithmetic operation should be performed.
- The result is displayed on the command line.
- A division-by-zero check prevents an invalid division operation.
- An invalid-operator message is displayed when an unsupported operator is entered.

5. Features

- Addition
- Subtraction
- Multiplication
- Division
- Division-by-zero error handling
- Invalid operator handling

6. Sample Output

```
===== SIMPLE CALCULATOR =====
Enter value of A: 20
Enter value of B: 10
```

Enter operator (+, -, *, /): +
Result: 30.0

7. Result

The calculator successfully performs the four basic arithmetic operations and provides messages for invalid operator input and division by zero.

8. Conclusion

This project demonstrates practical use of Python fundamentals. It provides a simple foundation for understanding input handling, conditional logic, arithmetic operations, and basic error handling.

9. Repository Contents

The GitHub repository should contain the Python source code, screenshots of program outputs, this report, and a detailed README.md describing the project and methodology.
